## C++ Introduction:

What is C++?

C++ is a cross-platform language that can be used to create high-performance applications.

C++ was developed by "Bjarne Stroustrup" as an extension to the C language.

C++ gives programmers a high level of control over system resources and memory.

: history (37) HQ

## Why Use C++

C++ is one of the world's most popular programming languages.

C++ can be found in today's operating systems, Graphical User Interfaces, and embedded systems.

C++ is an object-oriented programming language which gives a clear structure to programs.

and allows code to be reused, lowering development costs.

C++ is portable and can be used to develop applications that can be adapted to multiple platforms.

: primitive data types

## Difference between C and C++

C++ was developed as an extension of C, and both languages have almost the same syntax.

The main difference between C and C++ is that C++ supports classes and objects, while C does not.

## C++ Get Started :

To start using C++, you need mainly two things:

- A text editor, like Notepad, to write C++ code.
- A compiler, like GCC, to translate the C++ code into a language that the computer will understand.

Page No.			
Date			

## C++ Syntax :

Example ↴

```
#include <iostream>
using namespace std;
```

```
int main () {
```

```
cout << "Hello World!";
```

```
return 0;
```

## C++ Output :

Example ↴

```
#include <iostream>
```

```
using namespace std;
```

```
int main ()
```

```
{ cout << "Hello World!" ; }
```

```
return 0;
```

## Practice Example ↴

```
#include <iostream>
```

```
using namespace std;
```

```
cout << "Brown Bear" >> fud;
```

```
int main ()  
{  
    cout << "Hello World!";  
    cout << " I am learning C++";  
    return 0;  
}
```

## C++ Comments :

Comments can be used to explain C++ code, and to make it more readable. It can also be used to prevent execution when testing alternative code. Comments can be single-lined or multi-lined.

### Single-line Comments :

Single-line comments start with two forward slashes (//).

Any text between // and the end of the line is ignored by the compiler.

This example uses a single-line comment before a line of code:

### Example ↴

```
// This is a comment  
cout << "Hello World!";
```

Page No.	
Date	

## Multi-line comments :

backgrounds are available with /\* and \*/.

Multi-line comments start with /\* and ends with \*/.

Any text between /\* and \*/ will be ignored by the compiler:

## Example :-

/\* The code below will print the words Hello World!

to the screen, and it is amazing

\*/

cout << "Hello World!";

## C++ Variables :

Variables are containers for storing data values.

In C++, there are different types of variables for example:

- int → Stores integers (whole numbers), without decimals, such as 123 or -123

- double → Stores floating point numbers, with decimals, such as 19.99 or -19.99

- **char** → Stores single characters, such as 'a', or 'B'. Char values are surrounded by single quotes.
- **String** → Stores text, such as "Hello World". String values are surrounded by double quotes.
- **bool** → Stores values with two states; true or false.

### Declaring variables:

To create a variable, specify the type and assign it a value:

#### Syntax ↴

```
type variablename = value;
```

#### Example ↴

Create a variable called mynum of type int and assign it the value 15:

```
int mynum = 15;
```

```
cout << mynum;
```

Page No.	
Date	

## Other Types

### Example ↴

```
int myNum = 5;
```

Integer (Whole number without decimals)

```
double myFloatNum = 5.99;
```

Floating point number (With decimals)

```
char myLetter = 'Q';
```

character

```
string myText = "Hello";
```

String (Text)

```
bool myBoolean = true;
```

Boolean (True or False)

### Display Variables :

The `cout` object is used together with the `<<` operator to display variables.

To combine both text and a variable, separate them with the `<<` operator:

### Example ↴

```
int myAge = 35;
```

```
cout << "I am " << myAge << " years old.";
```

## Add Variables Together :

Example ↴

```
int x = 5;  
int y = 6;  
int sum = x + y;  
cout << sum;
```

## C++ Declare Multiple Variables :

To declare more than one variable of the same type, use a comma-separated list:

Example ↴

```
int x = 5, y = 6, z = 50;  
cout << x + y + z;
```

## One Value to Multiple Variables :

Assign the same value to multiple variables in one line:

Example ↴

```
int x, y, z;  
x = y = z = 50;  
cout << x + y + z;
```

Page No.		
Data		

## C++ Identifiers :

All C++ variables must be identified with unique names

These unique names are called IDENTIFIERS.

Identifiers can be short names (like x and y) and more descriptive names (age, sum, totalvolume).

### Example ↴

// Good

```
int minutesperHour = 60;
```

// OK, but not so easy to know what m actually is  
understand what I'm actually is  
int m = 60;

## C++ Constants :

When you do not want others to change existing variable values, use the const keyword (this will declare the variable as "constant", which means unchangeable and read-only):

Example ↴  
const int myNum = 15; // myNum

It will always be 15 : error: read-only variable 'myNum' used

`myNum = 10; // error: assignment of read-only variable 'myNum'`

## C++ User Input

`cin` is a predefined variable that reads data from the keyboard with the extraction operator (`>>`)

### Example 7

```
int x;
cout << "Type a number: ";
cin >> x;
cout << "Your number is: " << x;
// Display the input value
```

### \* Good To Know

`cout` is pronounced "see-out". Used for output, and uses the insertion operator (`<<`)

`cin` is pronounced "see-in". Used for input, and uses the extraction operator (`>>`)

Page No.		
Date		

## Example 7

```
int x, y;
int sum;
cout << "Type a number : ";
cin >> x;
cout << "Type another number : ";
cin >> y;
sum = x + y;
cout << "Sum is : " << sum;
```

## C++ Data Types:

A variable in C++ must be a specified data type:

### Example 1

```
int myNum = 5; // Integer (Whole number)
float myFloatNum = 5.99; // Floating point number
double myDoubleNum = 9.98; // Floating point number
char myLetter = 'D'; // Character
bool myBoolean = true; // Boolean
```

Page No.		
Date		

String myText = "Hello"; //

String

## Basic Data Types

Data Types : size domain Description

boolean 1 Stores true or false

byte 1 Stores false values

char 1 Stores a single character/letter/number, or ASCII values

int 2 or 4 Stores whole numbers, without decimals

bytes

float 4 Stores fractional numbers, containing one or more decimals. sufficient for storing 6-7 decimal digits.

double

8 bytes

Stores fractional numbers, containing one or more decimals. sufficient for storing

## Scientific Numbers :

A Floating point numbers can also be a scientific number with "e" to indicate the power of 10:

### Example ↴

```
float f1 = 35e3; // without specifying trailing
```

```
double d1 = 12E4; // trailing zero
```

```
cout << f1; // will print 35000
```

```
cout << d1; // will print 120000
```

## C++ Boolean Data Types :

A boolean data type is declared with the `bool` keyword and can only take the values `true` or `false`.

When the value is returned `true = 1` and `false = 0`.

### Example ↴

```
bool isCodingFun = true;
```

```
bool isfishTasty = false;
```

```
cout << isCodingFun; // outputs 1 (true)
```

`cout << isfishTasix; // outputs 0 (false)`

## C++ character Data Types :

The `char` data type is used to store a single character. The character must be surrounded by single quotes, like '`'A'`' or '`'c'`'.

### Example ↴

`: printf("HelloWorld")`

`char myGrade = 'B';`

`cout << myGrade;`

## C++ Operators :

Operators are used to perform operations on variables and values.

We use the `+` operator to add together two values:

### Example ↴

`int x = 100 + 250;`

`int x = 100 + 250;`

**ex-①**

```
int sum1 = 100 + 50;
```

$$150 \quad (100 + 50)$$

```
int sum2 = sum1 + 250;
```

$$400 \quad (150 + 250)$$

```
int sum3 = sum2 + sum1;
```

$$800 \quad (400 + 400)$$

## Arithmetic Operators :

Arithmetic operators are used to perform common mathematical operations.

Operator	Name	Description	Example
----------	------	-------------	---------

$+$  Addition Adds together two values

$-$  Subtraction Subtracts one value from another

\* Multiplication Multiplies two values

/ Division Devides one

~~operator % (modulus) returns value by another~~

%

Modulus

Returns the

$x \% y$

$E = X \% Y$

$E = X / Y$

Remainder

$E = X \% Y$

++ ~~Ans~~

Increment

Increases the

$++ x$

$E = X + 1$

$E = X + 1$

value of a variable by 1

$E = X + 1$

-- ~~Ans~~

Decrement

Decreases

$-- x$

the value

$E = X - 1$

of a variable by 1

$E = X - 1$

## Assignment Operators :

Assignment Operators are used to assign values to variables.

In the example below, we use the assignment operator (=) to assign the value 10 to a variable called x:

### Example ↴

int x = 10;

Page No.		
Date		

## List of all assignment Operators :

Operator      Example      Same As

=       $x = 5$        $x = 5$

+=       $x += 3$        $x = x + 3$

-=       $x -= 3$        $x = x - 3$

\*=       $x *= 3$        $x = x * 3$

/=       $x /= 3$        $x = x / 3$

%=       $x \% = 3$        $x = x \% 3$

&=       $x \& = 3$        $x = x \&$

^=       $x ^= 3$        $x = x ^ 3$

^=       $x ^= 3$        $x = x ^ 3$

>>=       $x >> = 3$        $x = x >> 3$

<<=       $x << = 3$        $x = x << 3$

Page No.	
Date	

## Comparison Operators :

Comparison Operators are used to compare two values (or variables). This is important in programming.

### Example ↴

```
int x = 5;
```

```
int y = 3;
```

```
cout << (x > y); // returns 1 (true) because 5 is greater than 3
```

### List of all comparison operators :

Operator

Name

Example

$x == y$  Equal to

```
x == y
```

$\neq$

Not equal

```
x != y
```

$>$

Greater than

```
x > y
```

$<$

Less than

```
x < y
```

$\geq$

Greater than or equal to

```
x >= y
```

$\leq$

Less than or equal to

```
x <= y
```

## Logical Operators :

Logical operators are used to determine the logic between variables or values.

Operator	Name	Description	Example
----------	------	-------------	---------

	Logical and	Returns true if both statements are true	$x < 5 \& x < 10$
--	-------------	--	-------------------

	Logical or	Returns true if one of the statements is true	$x < 5    x < 4$
--	------------	---	------------------

!	Logical Not	Reverse the result, returns false if the result is true	$!(x < 5 \& x < 10)$
---	-------------	---	----------------------

## STRINGS :

Strings are used to storing text.

A string variable contains a collection of

Characters surrounded by double quotes:

Example ↴

Create a variable of type String and assign it a value.

String greeting = "Hello";

To use strings, you must include an additional header file in the source code, `<string>`

// Include the string library

// Create a String variable  
String greeting = "Hello";

String Concatenation:

The + Operator can be used between strings to add them together to make new string.  
This is called concatenation.

Example ↴

String firstname = "John";

Page No.	
Date	

```
String lastname = "Doe";
String fullname = firstname +
lastname;
cout << fullname;
```

#include <iostream> //include iostream.h

## Numbers and Strings:

Adding Numbers and Strings

C++ uses `operator +` for both addition and concatenation.

Numbers are added. Strings are concatenated.  
If you add two numbers, the result will be a number.

Example ↴

```
int x = 10;
```

```
int y = 20;
```

```
int z = x + y; // z will be integer
```

30 (an integer)

If you add two strings, the result will be a string concatenation:

Example ↴

```
String x = "Lo";
```

String y = "20"; // string is primitive data type

String z = x + y; // z will be

1020 (a string)

## String Length :

To get the length of a string, use the `length()` function.

### Example ↴

```
String txt = "ABCD EFGHIJKLMNOPQRSTUVWXYZ";
```

```
cout << "The length of the string is : " << txt.length();
```

## Access Strings :

The character in a strings by referring to its index number inside square brackets [ ]

### Example ↴

```
String myString = "Hello";
```

```
cout << myString[0];
```

// outputs H

Page No.		
Date		

## Change String Characters :

To change the value of a specific character in a string, refer to the index number, and use single quotes.

### Example ↴

```
soft print P to format soft add OT
String mystring = "Hello";
mystring[0] = 'J';
cout << mystring;
// Outputs Jello instead of Hello
```

## Special characters :

### Strings - Special characters :

C++ will misunderstand this :String, and generate an error.

```
String txt = "We are the so-called Vikings from the north.";
```

## Backslash escape character (\)

The backslash (\) escape character turns special characters into string characters.

Escape character : Result Description

\'

'

single quote

\"

"

Double quote

\

\

Backslash

Escape character by programmer when add

Example : with detail knowledge how business

program :: addition &amp; subtraction &amp; multiplication and more

String txt = "We are the so-called Vikings from the north.";

## User Input Strings:

It is possible to use the extraction operator `>>` on `cin` to store a string entered by a user.

Example :

```
string firstName;
cout << "Type your first name : ";
cin >> firstName; // get user input from the keyboard
```

```
cout << "Your name is : " << firstName;
```

// Type your first name : John  
 // Your name is : John

String Namespace :

Omitting Namespace :

The using namespace std line can be omitted and replaced with the std::line keyword, followed by the :: operator for string (and cout) objects.

### Example:

```
#include <iostream>
```

```
#include <string>
```

```
<< namespace std with cout in sideways of #include
```

```
int main()
```

```
{
```

```
std :: string greeting = "Hello";
```

```
std :: cout << greeting;
```

```
return 0;
```

```
}
```

## C++ MATH :

The `cmath` library contains a collection of mathematical functions such as `sqrt()`, `sin()`, `cos()`, etc. These functions help us perform various mathematical calculations.

### Max and min

The `max(x,y)` function can be used to find the highest value of `x` and `y`.

#### Example ↴

```
cout << max(5,10);
```

## C++ <cmath> Header

Other functions, such as `sqrt` (square root), `round` (rounds off a number) and `log` (natural logarithm), can be found in the `<cmath>` header file:

#### Example ↴

```
// Include the cmath library
```

```
#include <cmath>
```

```
(cout << sqrt(64);
```

```
(cout << round(2.6);
```

```
(cout << log(2);
```

Page No.		
Date		

## C++ Booleans

In programming, you will need a data type that can only have one of two values, like:

- Yes/No
- On/Off
- True/False

for this, C++ has a bool data type, which can take the values true (1) or false (0)

### Boolean Values

A boolean variable is declared with the bool keyword and can only take the values true or false.

#### Example ↴

```
bool isCodingFun = true;
```

```
bool isFishTasty = false;
```

```
(cout << isCodingFun; // Outputs 1 (true)
```

```
(cout << isFishTasty; // Outputs 0 (false)
```

From the example above, you can read that a true value returns 1, and false returns 0.

However, it is more common in to return a boolean value by comparing values and variables.

### C++ Boolean Expressions :

A Boolean expression returns a boolean value that is either 1 (true) or 0 (false).

This is useful to build logic, and find answers.

Use comparison operator, such as the greater than ( $>$ ) operator, to find out if an expression (or variable) is true or false.

### Example ↴

```
int x = 10 ; int y = 9 ;
```

cout << (x > y); // returns 1

(true), because 10 is higher than 9.

### Real life Example ↴

"Real life example"! Where we need to find out if a person is old enough to vote.

In the example below, we use the  $\geq$  comparison operator to find out if the age (25)

is greater than OR equal to the voting age limit, which is set to 18.

Example ↴

: program to check if 25 is greater than or equal to 18

int myAge = 25;

int votingAge = 18;

cout << (myAge >= votingAge); //

returns 1 (true), meaning 25 year olds are allowed to vote.

### C++ If...Else:

#### C++ Conditions and If Statements

C++ supports the usual logical conditions from Mathematics :

- Less than :  $a < b$

- Less than or equal to :  $a \leq b$

- Greater than :  $a > b$

- Greater than or equal to :  $a \geq b$

- Equal to :  $a == b$

- Not Equal to :  $a != b$

C++ has following conditional statements :

- Use if to specify a block of code to be

Page No.	
Date	

executed, if a specified condition is true.

test some time, surf in additional soft w.

- Use else to specify a block of code to be executed, if the same condition is False
- Use else if to specify a new condition to test, if the first condition is False
- Use switch to specify many alternative blocks of code to be executed.

## The if Statement

: 3/3 4.2

Use the if statement to specify a block of code to be executed if a condition is true.

### Syntax

if (condition)

{

// block of code to be executed

if the condition is true

}

\* IMPORTANT → if is in lowercase letters.

Uppercase letters (IF or IF) will generate an error.

Test two values to find out if 20 greater than

18. If the condition is true, print some text:

if (20 > 18) // block of code of 20 is greater than 18

Example : cout << "20 is greater than 18";

if (20 > 18) // block of code of 20 is greater than 18

{ cout << "20 is greater than 18"; }

cout << "20 is greater than

18"; // block of code of 20 is greater than 18

{ cout << "20 is greater than 18"; }

## C++ Else :

for more info: If and Else

If Then Else

The else statement

Else statement to specify a block of code to be executed if the condition is False.

## Syntax

if (condition)

{ // block of code to be executed if the condition is true }

else { // block of code to be executed

if the condition is false }

{ // block of code to be executed if the condition is true }

if the condition is false }

{ // block of code to be executed if the condition is true }

if the condition is false }

{ // block of code to be executed if the condition is true }

if the condition is false }

## Example ↴

```
int time = 20;
if (time < 18) {
    cout << "Good day.";
} else {
    cout << "Good evening.";
}
// Outputs "Good evening."
```

## C++ Else If :

### The Else If Statement

Use the else if statement to specify a new condition if the first condition is false.

### Syntax

```
if (condition) {
    // block of code to be executed
    if (condition1 is true) {
        // block of code to be executed
        if (condition2) {
            // block of code to be executed
        }
    }
}
```

If the condition1 is false and condition2 is true

```
else {
    // block of code to be executed
}
```

If the condition1 is false and condition2 is false

condition2 is False  
}

Example ↴

```
int time = 22;
if (time < 10) {
    cout << "Good morning.";
} else if (time < 20) {
    cout << "Good day.";
} else {
    cout << "Good evening.";
```

// outputs "Good evening."

C++ Short Hand If Else:

Short Hand If ... Else (Ternary Operator)

There is also a short-hand if else, which is known as the ternary operator. because it consists of three operands. It can be used to replace multiple lines of code with a single line. It is often used to replace simple if else statements.

Syntax

```
variable = (condition) ? expressionTrue : expressionFalse;
```

## Example ↴

```
int time = 20; // auto ka ai mazbar ka diliing gft
if (time < 18) {
    cout << "Good morning." ; // auto ka ai mazbar ka diliing gft
} else {
    cout << "Good evening." ; // auto ka ai mazbar ka diliing gft
}
```

## C++ SWITCH :

### C++ Switch Statements

switch statement to select one of many code to be executed.

#### Syntax

```
switch (expression) {
```

case x:

// code block

break;

case y:

// code block

break;

default:

// code block

}

This is how it works:

- The switch expression is evaluated once for each case.
- The value of the expression is compared with the values of each case.
- If there is a match, the associated block of code is executed.
- The break and default keywords are optional, and will be described later in this chapter.

Example ↴

```
int day = 4;
switch (day) {
    case 1:
        cout << "Monday";
        break;
    case 2:
        cout << "Tuesday";
        break;
    case 3:
        cout << "Wednesday";
        break;
    case 4:
        cout << "Thursday";
        break;
    case 5:
```

```

cout << " Friday ";
break;
}
// outputs " Thursday " (day 4)

```

## The Break Keyword

When C++ reaches a **break** keyword, it breaks out of the switch block.

This will stop the execution of more code and case testing inside the block.

When a match is found, and the job is done, it's time for a break. There is no need for more testing.

## The Default Keyword

The **default** keyword specifies some code to run if there is no case match:

### Example ↴

```

int day = 4;
switch (day) {
    case 6:
        cout << " Today is Saturday ";
}

```

```

break;           ; " uphira" >> finn;
case 7;          D ; word
cout << " Today is sunday";   }

break;           ( uphira ) cout << " uphira" >> finn;
default;         D ; word
cout << " Looking forward to
the weekend";   break; cout << " uphira" >> finn;
};

// outputs " Looking forward to
the weekend"

```

### C++ While Loop:

Loops can execute a block of code as long as a specified condition is reached.

Loops are handy because they save time, reduce errors, and they make code more readable.

The while loop loops through a block of code as long as specified condition is true.

### Syntax

while (condition) {

// code block to be executed

}

for (initialization;

condition; update)

{} // code block to be executed

## Example ↴

```
int i = 0;
while (i < 5) {
    cout << i << endl;
    i++;
}
```

## C++ Do/While Loop:

### The Do/While Loop

The do/while loop is a variant of the while loop. This loop will execute the code block once, before checking if the condition is true, then it will repeat the loop as long as the condition is true.

### Syntax

```
do {
    // code block to be executed
}
```

```
while (condition);
```

## Example ↴

```
int i = 0;
do {
    cout << i << endl;
    i++;
}
```

```
cout << i << "\n";
    i++;
```

```
{}
while ( i < 5 );
```

## C++ For Loop :

Use the for loop instead of a while loop.

### Syntax

```
for ( Statement1; Statement2;
```

```
Statement3 ) {
```

// code block to be executed

};

### Example 1

```
for ( int i = 0; i < 5; i++ ) {
```

```
    cout << i << "\n";
```

```
}
```

### Nested Loops

It is also possible to place a loop inside another loop. This is called a nested loop.

The "inner loop" will be executed one time for each iteration of the "outer loop."

Example ↴

```
{ randomVar : i, for( ; i < n) do
    cout << "Outer: " << i << endl;
```

```
// Outer loop
for (int i=1; i<=2; ++i) {
    cout << "Outer: " << i << endl;
}
```

// Executes 2 times : output: Outer. 1Outer 2Outer

records // Inner loop i here represents inner

```
"file" for (int j=1; j<=3; ++j) {
    cout << "Inner: " << j << endl;
}
```

"\n"; // Executes 6 times (2 \* 3)

email of file at n10. m10) for each record add

{} the below code contains two loops begin from

## The ForEach Loop

There is also a "for-each loop" which is used exclusively to loop through elements in an array.

### Syntax

```
for (type variableName :
```

```
arrayName) {
```

// code block to be executed

{} it means it will print elements from 0 to n-1

which is from 0 to n-1 without having a

Example ↴ can't add in middle from out

```
int myNumbers[5] = {10, 20, 30, 40, 50,};
```

```
for(int i : myNumber) {
    cout << i & "\n";
}
```

### C++ Break And Continue :

Break Statement used in an earlier chapter of this tutorial. It has been used to "Jump out" of a Switch Statement.

The break statement can also be used to jump out of a loop.

### Example ↴

```
for (int i=0; i<10; i++) {
    if (i==4) {
        break;
    }
    cout << i << "\n";
}
```

### C++ Continue

The continue statements breaks one iteration if a specified condition occurs, and continues with the next iteration in the loop.

## Example ↴

```
for (int i = 0; i < 10; i++) {
    if (i == 4) {
        continue;
    }
    cout << i << endl;
}
```

## Break and Continue in While Loop

Use break and continue in while loops.

### Break Example ↴

```
int i = 0;
while (i < 10) {
    cout << i << endl;
    i++;
    if (i == 4) {
        break;
    }
}
```

### Continue example ↴

```
int i = 0;
while (i < 10) {
    if (i == 4) {
```

A circular yellow icon containing a cartoon-style portrait of a man with dark hair and glasses, wearing a black hoodie with a white bat logo on it.

```
    itt;  
    continue;  
}  
    {  
        if (Hi < op.size() &amp; theta == itt) rot  
        cout << i << "\n";  
        if (ll == i) ji  
        itt;  
    }  
};  
cout << "OK" >> i >> fun;
```

## C++ Arrays

Arrays are used to store multiple values in a single variable, instead of declaring separate variables for each value.

To declare an array, define the variable type, specify the name of the array followed by square brackets and specify the number of elements it should store: i) `int arr[10]`

String Cars [4];

## Access the Elements of an Array

Access an array element by referring to the index number inside square brackets [ ].

This statement assesses the value of the first element in cars:

Example ↴

```
String cars[4] = {"Volvo", "BMW",  
"Ford", "Mazda"};  
cout << cars[0];  
// Outputs Volvo
```

Change an Array Element

To change the value of specific element, refer to the index number.

```
cars[0] = "Opel";
```

Example ↴

```
String cars[4] = {"Volvo", "BMW",  
"Ford", "Mazda"};  
cars[0] = "Opel";  
cout << cars[0];  
// Now outputs Opel instead of Volvo.
```

Loop Through an Array

Loop through the array elements with the For loop.

## Example ↴

```
String cars[5] = {"volvo", "BMW", "Ford", "Mazda", "Tesla"};
for (int i = 0; i < 5; i++) {
    cout << cars[i] << endl;
}
```

C++ Array

## C++ Omit Array size :

## Omit Array size

The compiler is smart enough to determine the size of the array based on the number of inserted values:

```
String cars[] = {"volvo", "BMW", "Ford"}; // Three array elements
```

## Example ↴

```
String cars[3] = {"volvo", "BMW", "Ford"};
// Also three array elements.
```

## C++ Array Size

Get the size of an array

To get the size of an array, you can use the `sizeof()` operator:

Example ↴

```
int myNumbers[5] = {10, 20, 30, 40, 50};
```

```
cout << sizeof(myNumbers);
```

Result: 20

## Loop Through an Array With sizeof()

In Arrays and Loops chapter, we wrote the size of the array in the loop condition ( $i < 5$ ).

This is not ideal, since it will only work for arrays of a specified size.

By using the `sizeof()` approach from the example above, we can now make loops that work for arrays of any size, which is more sustainable.

Example ↴

```
int myNumbers[5] = {10, 20, 30, 40, 50};
```

```
40, 50};
```

```
for (int i = 0; i <
```

```
sizeof(myNumbers) / sizeof(int);
```

```
i++) {
```

```
cout << myNumbers[i] << endl;
```

```
}
```

## C++ Multi-Dimensional Arrays:

### Multi-Dimensional Arrays

A multi-dimensional array is an array of arrays.

To declare a multi-dimensional array, define the variable type, specify the name of the array followed by square bracket which specifies how many elements the main array has, followed by another set of square brackets which indicates how many elements the sub-arrays have.

```
String letters[2][4];
```

```
String letters[2][4] = {
```

```
{"A", "B", "C", "D"},
```

```
{ "F1", "F2", "G", "H"}
```

```
};
```

Arrays can have any number of dimensions. The more dimensions an array has, the more complex the code becomes.

String letters [2] [2] M [2] = { pyramid7, momod7 }

lett. at { 25798, 4093919 } M [2] to print lett. symbol of 7

lett. at { "A", "B" } M [2] to address symbol  
{ "C", "D" }

}; { } multi-dimensional Access 2 - algorithm7

{ "E", "F" }, { "G", "H" }

}; { }; multi-dimensional Access 3 - algorithm7

{ "I", "J" }, { "K", "L" }

; { }; multi-dimensional Access 4 - algorithm7

## Access the Elements of a Multi-dimensional Array

To access an element of a multi-dimensional array, specify an index number in each of the array's dimensions. In the statement "letters[0][2]", 0 is the index of the first row, and 2 is the index of the third column.

This statement accesses the value of the element in the first row (0) and third column (2) of the letters array.

### Example ↴

String letters [2] [4] = {

{ "A", "B", "C", "D" }, { "E", "F", "G", "H" }

}; { } multi-dimensional Access 1 - algorithm7

cout << letters [0] [2]; // outputs "C" = first row

## Change Elements in a Multi-Dimensional Array

To change the value of an element, refer to the index number of the element in each of the dimensions.

### Example ↴

String letters [2][4] = {

{"A", "B", "C", "D", }

{"E", "F", "G", "H", }

{};

letters [0][0] = "Z";

cout << letters[0][0]; // Now

outputs "Z" instead of "A"

## Loop Through a Multi-dimensional Array

To loop through a multi-dimensional array, you need one loop for each of the array's dimensions.

### Example ↴

String letters [2][4] = {

{"A", "B", "C", "D", }

{"E", "F", "G", "H", }

{};

for (int i = 0; i < 2; i++) {

Page No.	
Date	

```
for (int i = 0; i < 4; i++) {
    cout << letters[i][j] <<
    "In";
}
}
```

Why Multi-Dimensional Arrays?  
 Multi-dimensional arrays are great at representing grids. This example shows a practical use for them. multi-dimensional array to represent a small game of Battleship.

## C++ Structures (Struct)

### C++ Structures

Structures are a way to group several related variables into one place. Each variable in the structure is known as a Member of the structure.

Unlike an array, a structure can contain many different data types (int, string, bool, etc.)

### Create a Structure

To create a structure, use the `struct` keyword and declare each of its members inside curly braces.

Page No.		
Data		

The declaration, specify the name of the structure variable (`mystructure`) in the below example ↴

```
struct {                                // Structure
    declaration
    int mynum;                          // Member
    (int variable)
    String myString;                    // Member
    (String variable)
} myStructure;                         // Structure
variable
```

### Access Structure Members

To access members of a structure, use the dot syntax (`.`);

#### Example ↴

// Create a structure variable

called `mystructure`

```
struct {
    int mynum;
    String myString;
} myStructure;
```

// Assign values to members of

`myStructure` with `mynum = 1` and `myString = "Hello World!"`

```
myStructure.mynum = 1;
myStructure.myString = "Hello World!";
```

```
// print members of mystructure
cout << myStructure.myNum << endl;
"\\n";
cout << myStructure.myString << endl;
"\\n";
```

## One Structure in Multiple Variables

Use a comma (,) to use one structure in many variables.

```
D) Structure definition before it is used
int myNum;
String myString;
{ myStruct1, myStruct2, "prefix" = first variable
myStruct3; // multiple structure
variable separated with commas
```

## Named Structure

By giving a name to the structure, you can treat it as a data type. This means that you can create variables with this structure anywhere in the program at any time.

To create a named structure, put the name of the structure right after the struct keyword.

```
struct myDataType { // This structure is named "myDataType"
    int myNum;
    string myString;
};
```

## C++ References:

### Creating References:

A reference variable is a "reference" to an existing variable, and it is created with the `&` operator.

```
string Food = "pizza"; // Food Variable
string &meal = Food; // reference to food
```

### Example:

```
string Food = "pizza";
string &meal = Food;
cout << food << "\n"; // outputs pizza
cout << meal << "\n"; // outputs pizza
```

Page No.	
Date	

## C++ Memory Address:

### Memory Address

When a variable is created in C++, a memory address is assigned to the variable. And when we assign a value to the variable, it is stored in this memory address.

Use the & Operator, and the result will represent where the variable is stored.

### Example ↴

String Food = "pizza";

cout << &Food; // outputs  
0xb6fed4

### C++ pointers :

### Creating pointers

Memory address of a variable by using the & Operator:

### Example ↴

String Food = "pizza"; // A food variable of type string

`cout << food; // outputs the value of food (pizza)`

`cout << &food; // outputs the memory address of food (0x6dfed4)`

## C++ Reference

### Get Memory Address and Value

Use the pointer to get the value of the variable, by using the \* operator.

### Example ↴

```
String Food = "pizza"; // variable declaration
String* ptr = &Food; // pointer declaration
```

// Reference: Output the memory address of Food with the pointer (0x6dfed4)

`cout << ptr << "\n";`

// Deference: Output the value of food with the pointer (pizza)

`cout << *ptr << "\n";`

Page No.	
Date	

## C++ Functions :

A function is a block of code which only runs when it is called.

functions are used to perform certain actions, and they are important for reusing code.

### Create a Function

C++ provides some pre-defined functions, such as **main()**, which is used to execute code. But you can also create own functions to perform certain actions.

### Syntax

```
void myfunction () {
    // Code to be executed
}
```

### Example ↴

```
// Create a function
void myfunction() {
    cout << "I just got executed!";
}
```

```
int main() {
    myfunction(); // call the
    function
```

```
    } return 0;
```

// outputs "I just got executed!"

## Function Declaration and Definition

- **Declaration** - The return type, the name of the function and parameters

- **Definition** - The body of the function (Code to be executed)

```
void myFunction() { // part of declaration
    // the body of the function
    // (definition)
}
```

## Example ↴

```
int main() {
```

```
    myFunction();
```

```
    return 0;
```

```
}
```

```
void myFunction() {
```

```
    cout << "I JUST got executed!";
```

```
}
```

// Error

## C++ Function Parameters:

### Parameters and Arguments

parameters act as variables inside the function.

parameters are specified after the function name, inside the parentheses.

### Syntax

```
void functionName (parameter1, parameter2, parameter3) {
    // Code to be executed
}
```

### Example ↴

```
void myfunction (String fname) {
    cout << fname <<
```

```
main () {
    myFunction ("Liam");
    myFunction ("Jenny");
    myFunction ("Ania");
    return 0;
}
```

// Liam Refines

// Jenny Refines

// Ania Refines

## C++ Default parameters

### Default Parameter Value

Default parameter value also use, by using the equals sign (=)

It uses also default value ("Norway"):

#### Example ↴

```
void myfunction( String country =  
"Norway" ) {  
    cout << country << endl;  
}  
  
int main() {  
    myfunction("Sweden");  
    myfunction("India");  
    myfunction();  
    myfunction("USA");  
    return 0;  
}
```

// Sweden

// India

// Norway

// USA

:("Swed") output will be

:("Ind") output will be

:("Nor") output will be

:("USA") output will be

Page No.	
Date	

## C++ Multiple Parameters:

### Multiple parameters

In this parameter you can add as many parameters as you want.

Example ↴

```
void myFunction (String Fname, int age) {
    cout << Fname << " Refsnes."
    << age << " years old.\n";
}
```

```
main () {
    myFunction (" Liam ", 3);
    myFunction (" Jenny ", 14);
    myFunction (" Ania ", 30);
    return 0;
}
```

```
// Liam Refsnes. 3 years old.
// Jenny Refsnes. 14 years old.
// Ania Refsnes. 30 years old.
```

## C++ Return keyword :

### Return Values

The void keyword, used in the previous page.

Indicates that the function should not return a value instead of void and use the return keyword inside the function.

Example ↴

```
int myFunction( int x ) {  
    return 5 + x;  
}
```

```
int main() {  
    cout << myFunction(3);  
    return 0;  
}
```

// Outputs 8 (5+3)

## C++ Functions - Pass By Reference

### Pass By Reference

This can be useful when you need to change the value of the arguments.

example ↴

```
void swapnums( int &x, int &y ) {  
    int z = x;
```

$x = y;$

$y = z;$

70} changing both will have changed their original values

```
int main() {
    int i, j, k;
    int firstNum = 10;
    int secondNum = 20;
}
```

```
cout << "Before Swap: " << firstNum << secondNum
<< endl;
cout << firstNum << secondNum
<< endl;
```

// Call the function, which will change the values of firstNum and secondNum

```
swapNums(firstNum, secondNum);
```

```
cout << "After Swap: " << endl;
```

```
cout << firstNum << secondNum
<< endl;
```

```
return 0;
}
```

C++ pass Array to a Function:

Pass Arrays as Function Parameters

Example ↴

```
void myFunction( int myNumbers[] ) { }
```

```

for (int i = 0; i < 5; i++) {
    cout << myNumbers[i] << endl;
}

int main() {
    int myNumbers[5] = {10, 20, 30,
    40, 50};
    myFunction(myNumbers);
    return 0;
}

```

## C++ Function Overloading

Function Overloading: multiple functions can have the same name with different parameters.

### Example ↴

```

int myFunction(int x)
float myFunction(float x)
double myFunction(double x,
double y)

```

## C++ Recursion

Recursion is the technique of making a function call itself.

This technique provides a way to break complicated problems down into simple problems which are easier to solve.

### Example ↴

```
int sum( int k) {
```

```
    if (k > 0) {
```

```
        return k + sum(k - 1);
```

```
    } else {
```

```
        return 0;
```

```
}
```

```
int main () {
```

```
    int result = sum (10);
```

```
    cout << result; // 55
```

```
    return 0;
```

```
}
```

### C++ OOP

#### C++ What is OOP?

OOP stands for object-oriented programming.

Procedural programming is about writing procedures or functions that perform operations on the data, while object-oriented programming is about

creating objects that contain both data and functions.

## Advantages Over procedural programming :

- OOP is faster and easier to execute
- OOP provides a clear structures for the programs.
- OOP helps to keep the C++ code DRY ("Don't Repeat yourself"), and makes the code easier to maintain, modify and debug.
- OOP makes it possible to create full reusable applications with less code and shorter development time.

## C++ What are classes and objects?

classes and objects are the two main aspects of object - oriented programming.

Class	Objects
Fruit	Apple
	Banana
	Mango

## C++ classes and Objects:

### C++ classes / Objects

C++ is an object-oriented programming language.

Everything in C++ is associated with classes and objects, along with its attributes and methods. For example → in real life, a car is an object. The car has attributes, such as weight and color, and methods, such as drive and brake.

### Create a Class

Use the class keyword.

### Example 1

```
class MyClass { // The class
```

public:  
specifier

int myNum;

Attribute (int variable)

String myString; //

Attribute (String variable)

?;

## Create an Object

In C++, an object is created from a class. We have already created the class named Myclass, so now we can use this to create objects.

To create an object of Myclass, specify the class name, followed by the object name.

To access the class attributes (mynum and mystring), use the dot syntax (.) on the object:

### Example ↴

```
class MyClass { // The class
public: // Access
    int mynum; // Attribute (intString); // Create an object
    Attribute (String) variable;
};

int main () {
    MyClass myobj; // Create an object of MyClass.
    // Access attributes and set values
}
```

```

myobj.myNum = 15; brand = Ford;
myobj.myString = "Some text"; D : PAPI = map();
// print attribute values
cout << myobj.myNum << "\n";
cout << myobj.myString;
return 0;
}
    
```

## Multiple Objects

// Create a car class with some attributes

```

class Car {
public:
    string brand;
    string model;
    int year;
};
    
```

int main() {

// Create an object of car

Car carobj1;

carobj1.brand = "BMW";

carobj1.model = "X5";

carobj1.year = 1999; // carobj1 is object of car

// Create another object of car

Car carobj2;

```

carobi2.brand = "Ford"; // = multivari.idnum
carobi2.model = "Mustang"; // print car.idnum
carobi2.year = 1969; // D U U

// print attribute values
cout << carobi1.brand << " " << carobi1.year;
carobi1.model << " " << D_U_U;
carobi1.year << "\n";
cout << carobi2.brand << " " <<
carobi2.model << " " <<
carobi2.year << "\n";
return 0;
}

```

## C++ Class Methods:

### Class Methods

Methods are Functions that belongs to the class.

There are two ways to define functions that belongs to a class.

- Inside class definition
- Outside class definition

We define a function inside the class, and name it "myMethod".

## Inside Example ↴

```
class MyClass { // The scope is limited to this class
    public: // Access specifier
        void myMethod() { // Method / Function defined inside the class
            cout << "Hello World!";
        }
};
```

## int main()

```
    MyClass myobj; // Create object of MyClass
    myobj.myMethod(); // Call the method
    return 0;
}
```

## Outside Example ↴

```
class MyClass { // The scope is limited to this class
    public: // Access specifier
        void myMethod(); // Method / Function declaration
};
```

// Method / Function definition outside the class

```

void myclass::mymethod() {
    cout << "Hello World";
}

int main() {
    myclass myobj; // Create an object
    myobj.mymethod(); // Call the method
    return 0;
}

```

## Parameters

### Example ↴

```

#include <iostream>
using namespace std;

class car {
public:
    int speed( int maxspeed );
};

int car::speed( int maxspeed ) {
    return maxspeed;
}

int main() {
}

```

Page No.	
Date	

```
Car myobj; // create an object
of Car
cout << myobj.speed(200); // call the method with an argument
return 0;
}
```

## C++ Constructors :

A constructor in C++ is a special method that is automatically called when an object of a class is created.

To create a constructor, use the same name as the class, followed by parentheses () :

### Example ↴

```
class MyClass {
public:
    MyClass() { cout << "Hello World!"; }
};

int main() {
```

Page No.		
Date		

```
MyClass myobj; // Create an object of MyClass
Object of MyClass (this will call the constructor)
the constructor)
return 0;
}
```

## Constructor parameters

Constructors can also take parameters (just like regular functions), which can be useful for setting initial values for attributes.

brand, model and year attributes, and a constructor with different parameters. Inside the constructor we set the attributes equal to the constructor parameters (brand=x, model=y, year=z).

### Example ↴

```
class Car { // The class
    public: // Access Specifier
        string brand; // Attribute
        string model; // Attribute
        int year; // Attribute
    car (string x, string y, int z) { // Constructor with parameters
        brand = x;
        model = y;
        year = z;
    }
}
```

```
model = y;
year = z;
};
```

```
int main() {
    // Create car objects and call the
    // constructor with different values
}
```

```
car corobil ("BMW", "X5", 1999);
car corobiz ("Ford", "Mustang",
1969);
```

```
// print values
cout << corobil.brand << endl << corobil.model << endl << corobil.year << endl;
cout << corobiz.brand << endl << corobiz.model << endl << corobiz.year << endl;
return 0;
}
```

## C++ Access Specifiers:

### Access Specifiers

You are quite familiar with the **public** keyword that appears in all of our class examples.

## C++ Inheritance :

### Inheritance

In C++, it is possible to inherit attributes and methods from one class to another. We group the "inheritance concept" into two categories.

- derived class (child) - the class that inherits from another class
- base class (parent) - the class being inherited from

To inherit from a class, use the `:` symbol

In the example below, the `car` class (child) inherits the attributes and methods from the `vehicle` class (parent):

### Example ↴

```
// Base class
class vehicle {
```

```
public:
```

```
String brand = "Ford";
```

```
void honk() {
```

```
cout << "Tut, tut! \n";
```

```
}
```

```
};
```

A circular yellow icon containing a cartoon-style portrait of a person with dark hair and glasses, wearing a black hoodie with a white bat logo.

**private:** : *privateaddrT* #D

// private attribute

int salary;

• *watercolor* (4)

myobi-setsalary (50000);

```
cout << myobj.getSalary();
```

return 0; // If you want to print address of

4

Why Encapsulation? maintainability and extensibility

- It is considered good practice to declare your class attributes as private. Encapsulation ensures better control of your data, because you can change one part of the code without affecting other parts.

- Increased security of data.

Page No.	
Date	

Example ↴

```
class MyClass {           // The class
public:                  // Access
    Specifier             // class members goes here
};
```

C++ Encapsulation :

### Encapsulation

The meaning of Encapsulation, is to make sure that "sensitive" data is hidden from users. To achieve this, you must declare class variables / attributes as private. You can provide public get and set methods.

### Access Private Members

To access a private attribute, use public "get" and "set" methods.

Example ↴

```
#include <iostream>
```

```
using namespace std;
```

```
class Employee {
```

```
void myFunction () {
    cout << "some content in
Parent class ;
}
```

```
// Another base class
class myotherclass {
public:
```

```
void myOtherFunction () {
    cout << "Some content in
another class ";
```

```
};
```

// Derived class

```
class mychildclass : public
myclass, public myotherclass
{};

int main () {
```

```
mychildclass myobj;
```

```
myobj.myfunction ();
```

```
myobj.myOtherfunction ();
```

```
return 0;
```

```
}
```

## C++ Inheritance Access

### Access Specifiers

```
cout << "some content in parent class.";
```

```
// Derived class (child)
```

```
class Mychild : public MyClass {
```

```
// Derived class (grandchild)
```

```
class MyGrandchild : public Mychild {
```

```
int main () {
```

```
MyGrandchild myobj;
```

```
myobj.myfunction();
```

```
return 0;
```

## C++ multiple Inheritance :

### Multiple Inheritance

Using a comma-separated list:

### Example,

```
// Base class
```

```
class MyClass {
```

```
public :
```

```
// Derived class
class car: public vehicle {
public:
    String model = "Mustang";
};

int main() {
    car mycar;
    mycar.honk();
    cout << mycar.brand << endl;
    mycar.model;
    return 0;
}
```

## C++ Multilevel Inheritance

### Multilevel Inheritance

A class can also be derived from one class, which is already derived from another class.

In the following example, MyGrandchild is derived from class MyChild.

### Example ↴

```
// Base class (parent)
class MyClass {
public:
    void myFunction() {
```

```

class pig : public Animal {
public:
    void animalsound () {
        cout << "The pig says: wee
wee\n";
    }
};

```

### // Derived class

```

class Dog : public animal {
public:
    void animalsound () {
        cout << "The dog says: bow
bow\n";
    }
};

```

### C++ Files :

#### C++ Files

The **fstream** library allows us to work with files.

To use the **fstream** library, include both the standard **<iostream>** AND the **<fstream>** header file.

```
myobj.bonus << "n"; A writing : 29/2/2023
return 0;
```

{

## C++ polymorphism :

### Polymorphism

Polymorphism means "many forms" and it occurs when we have many classes that are related to each other by inheritance.

For example, think of a base class called **Animal** that has a method called **animalsound()**. Derived classes of **Animal** could be **pigs**, **cats**, **Dogs**, **Birds** - And they also have their own implementation of **an animal sound**.

### Example ↴

```
// Base class
```

```
class Animal {
```

```
public:
```

```
void animalsound () {
```

```
cout << "The animal makes a sound\n";
```

```
}
```

```
};
```

```
// Derived class
```

Example ↴

// Base class

class Employee {

protected: // protected access specifier

int salary;  
};

// Derived class

class programmer : public Employee {

public:

int bonus;

void setsalary (int s) {

Salary = s;

int getsalary () {

return Salary;

}

int main () {

programmer myobj;

myobj.setsalary (50000);

myobj.bonus = 15000;

cout << "Salary:" <<

myobj.getsalary () << "\n";

cout << "Bonus:" <<

## Example ↴

Program ↴

```
#include <iostream>
```

```
#include <fstream>
```

There are three classes included in the `fstream` library, which are used to create, write or read files.

### Class

### Description

`ofstream`

Creates and writes to files

`ifstream`

Read from files

`fstream`

A combination of `ofstream` and `ifstream`: creates, reads, and writes to files.

### Create and Write To a File

To create a file, use either the `ofstream` or

`fstream` class and, specify the name of the file.

To write to the file, use the insertion operator

`(<<).write()` with base at `(char*)` or `(int*)`

`(char*)` or `(int*)` or `(float*)` or `(double*)`

## Example ↴

```
#include <iostream>
#include <fstream>
using namespace std;

int main() {
    // Create and open a text file
    ofstream myFile("filename.txt");
}
```

// Write to the file

myFile << "Files can be tricky,  
but it is fun enough!";

```
// Close the file
myFile.close();
}
```

## Read a File

To read from a file, use either the **ifstream** or **fstream** class, and the name of the file.

Note that we also use a **while** loop together with the **getline()** function (which belongs to the **ifstream** class) to read the file line by line and to print the content of the file.

## Example ↴

```
// Create a text string, which is used to output the text file to screen
string myText;
```

```
// Read from the text file
```

```
ifstream
```

```
myReadfile("filename.txt");
```

```
// Use a while loop together with the getline() function to read the file line by line.
```

```
while (getline(myReadfile,
```

```
myText)) {
```

```
// Output the text from the
```

```
file
```

```
cout << myText;
```

```
}
```

```
// Close the file
```

```
MyReadfile.close();
```

## C++ Exceptions

When executing C++ code, different errors can occur:

coding errors made by the programmer, errors due to wrong input, or other unforeseeable

`throw exception; // Throw an exception when a problem arise`

```
{ catch () {
    // Block of code to handle
    errors
}}
```

### Handle Any Type of Exceptions (...)

If you do not know the throw type used in the try block, you can use the "three dots" syntax (...) inside the catch block, which will handle any type of exception.

#### Example ↴

```
try {
    int age = 15;
    if (age >= 18) {
        cout << "Access granted - you
are old enough!";
    } else {
        throw 505;
    }
}

catch (...) {
    cout << "Access denied - you must be at least
18 years old.\n";
}
```

things.

When an error occurs, C++ will normally stop and generate an error message. The Technical term for this is: C++ will throw an exception.

### C++ try and catch

Exception handling in C++ consist of three keywords: try, throw and catch.

The try statement allows you to define a block of code to be tested for errors while it is being executed.

The throw keyword throws an exception when a problem is detected, which lets user create a custom error.

The catch statement allows you to define a block of code to be executed, if an error occurs in the try block.

The try and catch keywords come in pairs.

### Example ↴

```
try {
    // BLOCK OF CODE TO TRY
}
```
